# ICA0002: IT Infrastructure Services

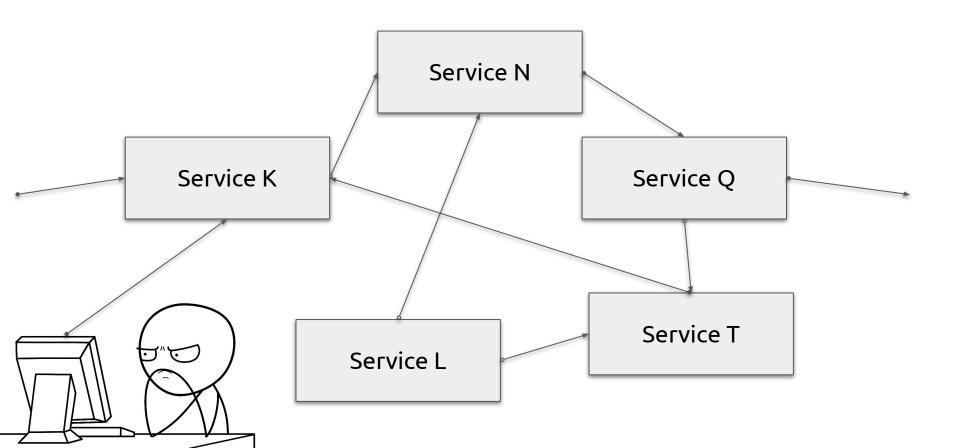

# Troubleshooting

Roman Kuchin Juri Hudolejev 2022

### Troubleshooting infrastructure services

- 1. Identify the misbehaving component
- 2. Identify the problem
- 3. Find the acceptable solution
- 4. Fix it!

# Identify the misbehaving component

## Troubleshooting infrastructure services

- Identify the misbehaving component ✓
- 2. Identify the problem
- 3. Find the acceptable solution
- 4. Fix it!

# Identify the problem

"I did everything correctly but it doesn't work!" -- is **not** a problem definition

#### Most common problems:

- Service is not running
- Service is running but not working correctly
- Service cannot communicate with another service

# Problem:

Service is not running

How to detect, option 1:

```
ps ax | grep <my-process-name>
```

- **ps** lists running OS processes
- grep filter out all but your service process

The simplest and fastest option to detect if the service is running

Example command to check if process is running:

```
ps ax | grep nginx
```

Example output if the process is running:

```
883 ? Ss 0:00 nginx: master process /usr/sbin/nginx -g ...
902 ? S 0:00 nginx: worker process
1636 pts/0 S+ 0:00 grep --color=auto nginx
```

Example output if the process is not running:

```
1638 pts/0 S+ 0:00 grep --color=auto nginx
```

How to detect, option 2:

```
systemctl status <my-service-name>
```

Alternative:

```
service <my-service-name> status
```

Both provide more details about the service and also some logs

Note: process, DEB package and Systemd unit names may differ! Example: mysqld / mysql-server / mysql.

Example command to check service status:

```
systemctl status mysql
```

Example output if the service is running:

```
...
Active: active (running) since Sat 2019-10-26 11:51:03 UTC ...
```

Example output if the service is not running:

```
Active: inactive (dead) since Sat 2019-10-26 12:20:08 UTC ...
```

#### Most common causes:

- Service failed to start because of configuration issues
- Service failed to start because of lack of file permissions
- Service failed to start because the port in binds to is already taken
- Service did not start after the machine reboot
- You forgot to start the service :)

# Configuration syntax problems

How to detect:

```
nginx -t
apache2ctl -t (or apache2ctl configtest)
named-checkconf; named-checkzone
visudo -cf /etc/sudoers.d/my-user
```

Service built-in config checkers

The best way to check the configuration syntax of the existing files

Only a few services have this option :(

## Configuration syntax problems

Example command to check the service configuration syntax:

```
nginx -t
```

Example output if the configuration syntax is correct:

```
nginx: the configuration file /etc/nginx/nginx.conf syntax is ok
nginx: configuration file /etc/nginx/nginx.conf test is successful
```

Example output if the configuration syntax is not correct:

```
nginx: [emerg] unknown directive "rooot" in /etc/nginx/sites-enabled/default:4
nginx: configuration file /etc/nginx/nginx.conf test failed
```

## Configuration syntax problems

#### How to avoid:

```
ansible.builtin.copy:
    src: nginx-site.conf
    dest: /etc/nginx/sites-enabled/default
    validate: nginx -t -c %s
```

Validate the configuration **before** changing the actual file on server

More examples for sudo, SSH etc.:

- https://docs.ansible.com/ansible/latest/collections/ansible/builtin/copy\_module.html
- <a href="http://docs.ansible.com/ansible/latest/collections/ansible/builtin/template\_module.html">http://docs.ansible.com/ansible/latest/collections/ansible/builtin/template\_module.html</a>

#### Ansible validation: a common mistake

```
# File: tasks/main.yaml
  - ansible.builtin.copy:
      src: default
      dest: /etc/nginx/.../default
      validate: nginx -t -c %s
    notify:
      - Restart Nginx
# File: handlers/main.yaml
  - name: Restart Nginx
    ansible.builtin.service:
      name: nginx
      state: restarted
```

```
# File: tasks/main.yaml
  - ansible.builtin.copy:
      src: default
      dest: /etc/nginx/.../default
    notify:
      - Check Nginx config
      - Restart Nginx
# File: handlers/main.yaml
  - name: Check Nginx config
    ansible.builtin.command: nginx -t
  - name: Restart Nginx
    ansible.builtin.service:
      name: nginx
      state: restarted
```

### Starting service automatically

Common practice in the Debian world:

- Start and enable the service automatically during DEB package installation

Do not rely on this behavior! This is just a convention, not a law

The Ansible way to ensure that the service is started and enabled on boot:

ansible.builtin.service:

name: nginx

state: started

enabled: yes

# Service is running but

Problem:

Service is running but not working correctly

#### Examples:

- Key-based SSH is configured but it is still asking for a password on login
- Nginx should listen on port 8080 but it is only listening on 80
- User root can log in to MySQL but user elvis can not
- Bind should transfer entire zone but it only resolves individual addresses
- Script should backup these three directories but it backs up only this one
- etc.

#### How to detect:

- No silver bullet exists -- every service has its own specifics
- Make sure that service is actually running
- Check configuration
  - Almost certainly a configuration **logic** problem
  - If the daemon has started -- configuration syntax is okay
- Check logs
  - Use verbose (debug) mode -- temporary measure! Disable once done debugging!
- Still not solved? Search for the solution in the Internet
  - Localize the problem: it is easier is to find a solution for exact problems
  - "Nginx is not working" vs. "Nginx is not listening on port 8080"

#### Logs:

- /var/log/<service-name>
- /var/log/syslog

Alternative commands for Systemd journal:

- journalctl -fu <service-name>
- journalctl -xn

# Hints for log monitoring

```
Follow logs:
```

```
tail -f /var/log/nginx/error.log /var/log/syslog
Only print needed logs (containing cron in this example):
grep -i cron /var/log/syslog
```

Filter out some lines (print all but lines containing **systemd** in this example):

```
grep -v systemd /var/log/syslog
```

#### Verbose (debug) mode:

- ansible-playbook -v infra.yaml
- curl -v http://localhost:8080
- wget -d http://localhost:8080
- ssh -vvv my-user@my-server

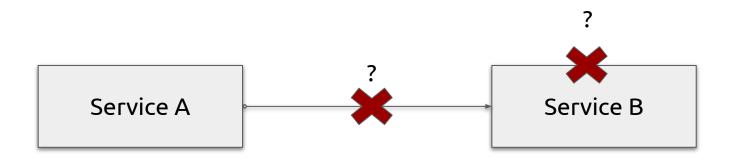

Nginx configuration file: error\_log /var/log/nginx/error.log debug;

^^^ you'll rarely need this; do not enable permanently in production!

# Service cannot communicate to

Problem:

another service

First thing: make sure both services are **running** and **working correctly** 

Next thing: detect, identify and fix connectivity issues

Common connectivity issues:

- Machine is not connected to the network
- Machine cannot reach another machine
- Service A cannot connect to another machine's port N
- Service B is listening on wrong interface and/or port

How to check if machine is connected to the network:

```
ping 1.1.1.1
```

Example output if the machine is connected (Ctrl+C to stop pinging):

```
64 bytes from 1.1.1.1: icmp_seq=3 ttl=56 time=9.70 ms
64 bytes from 1.1.1.1: icmp_seq=4 ttl=56 time=10.3 ms
...
```

Example output if the machine is not connected:

```
connect: Network is unreachable
```

How to check if machine can reach another machine:

ping <another-machine-address>

Alternative if ping to remote machine is blocked by firewall:

traceroute <another-machine-address>

How to check if one can connect to another machine's port:

nc -vz <another-machine-address> <port>

Alternative if **nc** is not available:

telnet <another-machine-address> <port>

Example command to check if service is listening on the remote port:

nc -vz 192.168.42.37 8080

Example output if the service is listening on the remote port:

Connection to 192.168.42.37 8080 port [tcp/http-alt] succeeded!

Example output if the service is not listening on the remote port:

nc: connect to 192.168.42.37 port 8080 [tcp/http-alt] failed: Connection refused

How to detect if service is listening on the correct port:

```
sudo ss -lptu # listening, process info, TCP, UDP
```

Needs admin privileges to list process names (-p option)

Alternative if **netstat** is not available:

sudo netstat -lptu

Example command to list all services listening on TCP ports:

```
sudo ss -lpt
```

Example output if the service is listening on the **public** interface:

```
        State
        Recv-Q
        Send-Q
        Local Address:Port
        Peer Address:Port
        Process

        LISTEN
        0
        0.0.0.0:22
        0.0.0.0:*
        users:(("ssh",pid=821,fd=7))

        LISTEN
        0
        0.0.0.0:80
        0.0.0.0:*
        users:(("nginx",pid=948,fd=13))

        LISTEN
        0
        0.0.0.0:8080
        0.0.0.0:*
        users:(("nginx",pid=948,fd=13))
```

Example output if the service is listening on the **local** interface:

```
LISTEN 0 0 127.0.0.1:3306 0.0.0.0:* users:(("mysqld",pid=946,...
```

## Troubleshooting infrastructure services

- Identify the misbehaving component ✓
- 2. Identify the problem ✓
- 3. Find the acceptable solution
- 4. Fix it!

### Finding the solution

Check service documentation:

```
- <service-name> --help example: ansible --help
- man <service-name> example: man nginx
- info <service-name> example: info ssh
- ansible-doc <module> example: ansible-doc apt
```

- Ask Google, DuckDuckGo, Bing etc.
- 3. Try <u>rubber duck debugging</u> -- not a joke, it really works
- 4. Ask a colleague for help

^^^ Strictly in **this** order!

## Troubleshooting infrastructure services
